TITLE: Superstrength structural steels

SOURCE: Nauchno-tehnicheskoye obshchestvo mashinostroitel'noy promyshlennosti. Sektsiya metallovedeniya i termicheskoy obrabotki. Metallovedeniye i termicheskaya obrabotka, no. 4, 1966, 18-22

TOPIC TAGS: ~~superstrength~~ structural steel, silicon containing steel, steel property / 45KhNM structural steel, 45KhMF structural steel, 45KhGS structural steel, 45KhGSNMF structural steel, 45KGS2N3M structural steel, 45KGS2MF structural steel

ABSTRACT: The effect of silicon, at contents of up to 2.2% on the structure and properties of alloy steels containing up to 0.8% carbon has been investigated. It was found that steel strength increases steadily with increasing silicon content. For instance, the strength of steel containing 0.2% silicon and 0.6% carbon, hardened and tempered at 400C, was 135 kg/mm<sup>2</sup>, while that of steel containing 2.2% silicon (other conditions being the same) was 195 kg/mm<sup>2</sup>. The effect of

Card 1/2

ACC NR: AT6031221

silicon is especially sharply pronounced in complex alloy steels. 45KhGSNFM, 45KhGS2N3M, and 45KhGS2MF complex alloy steels, hardened and tempered at 400C, had a tensile strength of 200—210 kg/mm<sup>2</sup>, a yield strength of 160—185 kg/mm<sup>2</sup>, an elongation of 8—10%, a reduction of area of 30—35%, and a notch toughness of 4—6 kgm/cm<sup>2</sup>. Even with low tempering (200C), when the tensile strength is well over 220 kg/mm<sup>2</sup>, the reduction of area and notch toughness remain fairly high: 27—33% and 4—6 mkg/cm<sup>2</sup>. Irreversible temper brittleness in these steels develops at high temperature. Therefore, they can be tempered at 250—400C without danger of embrittlement. [TD]

TITLE: Crystallization of nickel on the cathode in the electrolysis of chloride melts

SOURCE: Elektrokimiya, v. 2, no. 11, 1966, 1347-1349

TOPIC TAGS: metal crystallization, nickel, chloride, *electrolysis, cathode*

ABSTRACT: The experiments were carried out in a hermetically sealed cell in an atmosphere of purified and dried argon. The cell was placed in a massive metallic block to achieve a minimum temperature variation of the electrolyte. The temperature was measured with a high ohmic potentiometer to an accuracy of  $\pm 1^\circ\text{C}$ . The investigation was made under galvanostatic conditions on microcathodes with a surface of  $1.0 \times 10^{-3} \text{ cm}^2$  and  $7 \times 10^{-3} \text{ cm}^2$ . The amount of current passing in all the experiments was the same— $7.55 \times 10^{-4}$  ampere-hours/ $\text{cm}^2$ . After the end of polarization with a current of given strength, the electrode was withdrawn, washed in hot distilled water, then in alcohol and, finally, dried. The residue was examined under the microscope. Before each experiment, the cathode was polished anew. The investigations showed that the number of nickel crystal nuclei grows with an increase in current

Card 1/2

ACC NR: AF6035592

density and with a decrease in concentration of  $\text{NiCl}_2$  and in temperature. Dependence of the number of crystals on current density was always very close to linear, in all experiments and with different concentrations, at temperatures up to  $600^\circ\text{C}$ . The effect of nickel chloride concentration on the number of nuclei was verified at  $T = 520^\circ\text{C}$  for current densities of  $5.0 \times 10^{-2}$ ,  $3.38 \times 10^{-2}$ , and  $1.69 \times 10^{-2}$  amp/cm<sup>2</sup> over the concentration interval 0.00435-0.223  $\text{NiCl}_2$ . Clarification and filtration of fruit juices with the aid of Odessa green clay. E. G. Tomash and Fan-Yung. *Trudy Odessk. Tekhnol. Inst. Pishchevol. i Khimich. Prom. S. No. 2, 63-70 (1953)*; *Referat. Zhur., Khim.* 1954, No. 4241. — A study of the suitability of Odessa green clay for clarification and filtration of fruit juices (apple and grape) gave favorable results. Upon the contact of the fruit juice with a clay suspension, the juice colloids, carrying a pos. charge (proteins) are neutralized by the neg. charges of the clay particles. The double layer of the colloids carrying a neg. charge (pectin) becomes rearranged. In consequence, the colloids coagulate and settle out. For complete clarification, the juice was filtered through a layer of settled-out clay taken in a quantity of 125-55 g./sq. m. of filter area. Filtration lasted 40-50 min. during which 75 l. of juice passed through each sq. m. of filter surface. After this, the layer of clay is changed. Best results gave a clay activated by thermal treatment or treated with HCl and H<sub>2</sub>SO<sub>4</sub> of various concns. or with NaCl and H<sub>2</sub>SO<sub>4</sub>. The waste of this clarification and filtration is reduced to 8-10% of the wt. of grapes. Juice, thus treated, had a good color, flavor, and odor. Analyses of apple and grape juice clarified with variously treated clay are given. M. Hosen

Oxidation and dehydration of castor oil. A. K. Plisev and E. G. Tomson (Odessa Canning Technol. Inst.). *Zhur. Priklad. Khim.* (J. Applied Chem.) 23, 200-2 (1950). A series of expts. to produce a drying oil on dehydration of castor oil by downward passage of the latter at 1 ml./min. through a vertical Al tube (1-2 cm. X 100 cm.) heated over 50 cm. length by an electric furnace showed that the following optimum conditions should be used when 30-40 g. activated clay filler is used: 400° tube temp. and air feed countercurrent to oil at 300 l./hr. The product under these conditions readily forms a tough, clear colorless film on drying in air, and addns. of 0.16% MnO<sub>2</sub> and 0.48% PbO somewhat accelerate the drying process. G. M. Materials Presented (Cont.) SOV/1886

CONTENTS: This collection of reports was presented at the United Scientific Session on Metallogeny and Postulated Ore Occurrence Maps convoked by the Academy of Sciences in Alma-Ata, December, 1958. The reports deal with various aspects of compiling metallogenetic and ore occurrence maps as well as the methods and techniques of correlating geophysical exploration data. These reports deal only with non-ferrous metals. Three other reports delivered at the conference, which are included in this work were by Ye. Ye. Zhdanov, M. S. Shatalov, and Yu. K. Goretskiy. References accompany each article.

FOREWORD: This volume is intended for scientists, engineers, physicists, and biologists working in the production and peaceful utilization of atomic energy for professors and students of schools of higher technical education where the subject is taught; and for people interested in atomic science and technology.

CONTENTS: This is volume 3 of a 6-volume set of reports on atomic energy, presented by Soviet scientists at the Second International Conference on the Peaceful Uses of Atomic Energy, held in Geneva from September 1 to 13, 1958. Volume 3 consists of two parts. The first part, edited by A.I. Zubov, is devoted to geology, prospecting, concentration and processing of nuclear source material. The second part, edited by G.L. Zverev, includes 27 reports on metallurgy, metallurgy, processing technology of nuclear fuels and materials, and nuclear irradiation effects on metals. The titles of the individual papers in each part are listed in the table of contents. An official English language edition of the Conference proceedings. See SOV/2203 for the titles of the other volumes of the set.

On the Porosity of Uranium under the Influence of a Cyclic Heat Treatment.

PERIODICAL

(Razvitiye poristosti v urane pod deystviyem tsiklicheskoy termooorabotki. Russian).

Atomnaya Energiya, 1957, II/6, pp 520 .. 524 (U.S.S.R.)

ABSTRACT

1. Description of the method of cyclic heat treatment.

Uranium rods ( $\phi = 4 - 5$  mm,  $l = 4 - 5$  mm) are introduced into a small quartz tube. These are shut either in a vacuum of  $1,10^{-3}$  mm torr. or in helium under a superpressure of 1,3 atm. The samples are heated in the course of 32 sec. in a high frequency furnace and are cooled in running water or in the air flow within the next 18 sec. The periods 32 and 18 sec. correspond to the duration of one cycle,

2. Cyclic heat treatment within the range of the  $\alpha$ -phase, of uranium.

Some samples are taken from a piece of uranium, which has been pressed under  $650^{\circ}$  C (content of carbon is about 0,1 %). Then these samples are turned out and handled as stated under 1. During this time they are heated up to  $550-600^{\circ}$  C. After this procedure the following changes in the measurements of the samples concerned occur.

Card 1/3

89-6-5/24

On the Porosity of Uranium under the Influence of a Cyclic Heat Treatment.

Nr	length		$\Delta$ lin <sup>0</sup> / <sub>o</sub>	diameter			Nr of cycles
	before treatm. in mm	after treatm. in mm		bef. tr. in mm	after tr. in mm	$\Delta$ d in <sup>0</sup> / <sub>o</sub>	
1	4.02	4.26	6.0	4.11	4.02	-2.2	250
2	4.03	4.58	18.5	4.11	3.94	-4.1	500
3	4.00	4.89	22.0	4.11	3.86	-6.1	1000
4	4.07	5.30	31.0	4.06	3.77	-7.1	2000

Moreover, it was found, that after 2000 cycles the density of the uranium decreased by 3<sup>0</sup>/<sub>o</sub> and after 5000 cycles by 8<sup>0</sup>/<sub>o</sub>.

3. Cyclic heat treatment of uranium all the three phases.

Samples are taken from uranium (cont. of carbon about 0,1<sup>0</sup>/<sub>o</sub>), which has been compressed within the  $\gamma$ -phase and quenched in oil. These proofs

Card 2/3

On the Porosity of Uranium under the Influence of a Cyclic Heat Treatment. 89-6.5/24

are then heated cyclically (50 - 1000) up to 800°C and then cooled. The following changes were observed. a) The shape of the sample had changed considerably. b) Porosity increases under simultaneous reduction of density.

TITLE: Recrystallization of Uranium Subjected to the Action of a Cyclical Thermal Treatment (Rekristallizatsiya urana pod deystviyem tsiklicheskoy termoobrabotki)

PERIODICAL: Atomnaya energiya, 1958, Vol. 4, Nr 6, pp. 555-556 (USSR)

ABSTRACT: Recrystallization was investigated in the case of three types of uranium, i.e. uranium that had been hardened in the  $\gamma$ -phase, uranium drawn in the  $\beta$ -phase, and in molten uranium. Cyclical thermal treatment had the following parameters:  
Maximum temperature 540-550° C; minimum temperature 100° C; average velocity of heating 22°/s; average velocity of cooling 25°/s; time of heating at maximum temperature 12 - 13 s. Microstructure was obtained by electrolytic etching in the following solution:  
Acetic acid - 1 part; saturated aqueous solution of chromium anhydride (specific weight 1.50) - 1 part; water - 2 parts. X-ray pictures were taken by means of the device RKU-86 with cobalt radiation.

TITLE: Significance of geographic and geological methods in lunar studies

SOURCE: Kosmicheskiye issledovaniya, v. 1, no. 3, 1963, 460-464

TOPIC TAGS: lunar research, lunar geological study, lunar geographic study, lunar structure, lunar relief, lunar history, meteorite lunar theory, astronomy, moon

ABSTRACT: The report offers a brief review of lunar research to date, clarifies the significance of geographic and geological methods for future studies of lunar structure and relief, proposes close coordination of such methods (giving consideration to comparative terrestrial material) with astronomical methods, evaluates various studies of geographic and geological aspects completed thus far, and discusses the meteorite approach to an explanation of the evolution of lunar structure and relief. It is suggested that it will be impossible to clarify the origin of lunar structures and relief, or their pattern of distribution, without the participation of geologists, nor will it be feasible to compile adequate topographic, geographic or selenological-geological charts or diagrams. SUBJECT USSR/MATHEMATICS/Differential equations  
 AUTHOR TOMSON M.A.  
 TITLE On the problem of investigation of the orbital ranges of stability.  
 On a case of investigating the orbital stability of the solutions  
 of a system of differential equations.  
 PERIODICAL Vychislit.Mat.vychislit.Tech. 2, 151-208 (1955)  
 Vychislit.Mat.vychislit.Tech. 2, 209-229 (1955)  
 reviewed 6/1956

In the system of differential equations

$$(1) \quad \ddot{x} = 2ny + U_x, \quad \ddot{y} = -2nx + U_y$$

let  $n$  be constant and  $U = U(x,y)$  a given function. Let  $\dot{x}^2 + \dot{y}^2 = 2(U+h)$  be the Jacobian integral of  $h$ . An undisturbed trajectory  $T_0$  is assumed to be known. Its stability is to be investigated, let  $\delta F$  be the measured deviation of the perturbation normal to  $T_0$ ,  $s$  the arc length on  $T_0$ . Then new variables are assumed to be introduced by  $\delta f = [2(U+h)]^k \delta F$  and by  $d\sigma = [2(U+h)]^{2k - \frac{1}{2}} ds$ . Thereby  $k$  is an arbitrary constant. After these substitutions the first approximation of the perturbation equation is

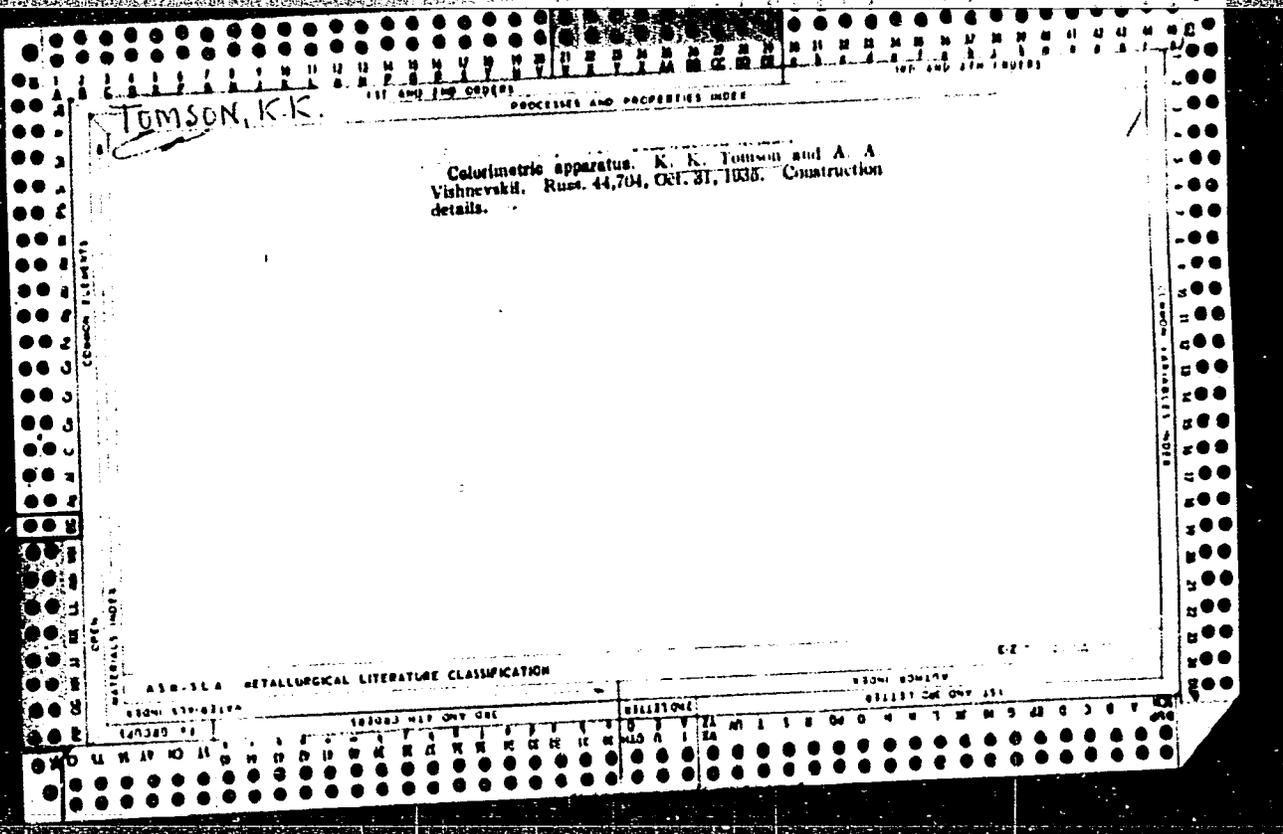

$$\frac{d^2 \delta f}{d\sigma^2} = D \delta f.$$

CARD 2/2 PG - 96/97

The sign of the coefficient  $D = D(x, y, \varphi, k)$  with  $\operatorname{tg} \varphi = \dot{y}/\dot{x}$ , introduced by Moisseev, gives an information on the stability.  $T_0$  is said to be orbitally stable (instable) if  $D < 0$  ( $D > 0$ ) is valid. Since  $D$  generally depends on  $\varphi$ , this magnitude is not only depending on the place. Domains in the  $(x, y)$ -plane, where sign  $D$  is independent of  $\varphi$ , are denoted ranges of orbital stability (instability). Orbital ranges of stability for  $k = 0$  (according to Jacobi),  $k = \frac{1}{2}$  (Zukovskij) and  $k = \frac{3}{2}$  (Moisseev) are investigated.

These domains of stability are calculated for the Hill's moon problem  $[U = \frac{3}{2}x^2 + (x^2 + y^2)^{1/2}]$  and explained by explicit tables and figures. Of special interest are the overlappings of the stability ranges which belong to different  $k$ . Track curves with periods  $2\pi/m$  are calculated for different  $m$  mainly in the second paper. In the moon case it is  $1/m = 12,3682$ . The results of this calculation of paths are distinctly represented in tables too.

In 1946 a new type of electro-aspirator was constructed at the Laboratory of Atmospheric Hygiene of the Institute of General and Public Hygiene, Academy of Medical Sciences. This contained an electrical source within the instrument making it adaptable for field use. It was portable and had a high degree of accuracy. The third model operated on 24 volts 30 watts, and held 20 alkali batteries with a capacity of 10 ampere hours each. During an 8-hour run the aspirator was able to accommodate 20 liters of air per minute.

Trace elements as a medico-biological and hygienic problem. N. M. Tomson. *Vestnik Akad. Med. Nauk S.S.S.R.* 1950, No. 5, 29-33. --A review of the influence of trace elements on living processes from the viewpoint of communal hygiene and physiology is presented. The contamination produced by waste products of industrial processes is discussed in relation to formation of endemic conditions for health disturbances. A more detailed account of the study of effects of Pb contamination is given. Analysis of tissues of exptl. animals (rats) taken in the vicinity of metal working plants, where Pb concn. in the air might be as high as 0.02 mg./cu. m., showed increase of 2-7-fold in comparison with controls (bones, liver, etc.); similar increases may be found in the flora of industrial regions. The laws governing self-purification of atmosphere from industrial waste. N. M. Tomson. *Gigiena i Sanit.* 1951, No. 3, 25-9.—Investigation of air pollution by Pb in territory near a plant producing lead pipe showed that high exhaust or vent pipes favor the spreading of contamination over larger areas. Numerous data in tabular form give typical results over several months. Typical results of studies of  $H_2SO_4$  and HCl plants are also cited; in these cases sampling was done directly under the smoke (or fumes) plumes and at graduated distances from the stack on both windward and lee sides according to prevailing winds. While concn. of gases of a  $H_2SO_4$  plant in the atm. was generally low (measurable in hundredths or tenths of %) in comparison with stack concn., the atm. concn. of Cl was high, possibly owing to its hygroscopicity and also to the relatively short stack used (15 m.). Title: On Isolation of Fluorescent Substances from Shale Tar

Original

Periodical: Izv. AN Est. SSR, 1955, No 3, 495-498

Abstract: Fluorescent substances (FS) of shale tar are isolated by filtration through a chromatographic column consisting of a glass tube 400 mm long, 8 mm in diameter filled with silica. A solution of 50 mg tar in one ml  $C_6H_6$  is introduced into the column and vaseline oil (VO) is poured on top. After 24 hours VO having passed the entire length of the column acquires an intensive yellow coloration. After 2 days the VO filtrate is pale yellow and on the third day the entirely transparent VO shows brilliant fluorescence. Further study of FS is conducted by fluorescence and absorption spectral analysis. The

## EXCERPTA MEDICA Sec. 17 Vol. 3/9 Public Health Sept. 57

2903. TOMSON N. M. Inst. of Sanit. and Hyg., Leningrad. \* Problems of sanitary control of the atmospheric air of Leningrad (Russian text) Tezisy dokladov na XIII vsesoyuznom s'ezde gigenistov, mikrobiologov, epidemiologov i infektzionistov, Moskva, 1956, 1 (68-70)

Measures applied in recent years to improve the atmospheric air of Leningrad resulted in decrease of air pollution by 30-35%. Testing of efficiency of two-step filters before and after installation in an electric power plant revealed a decrease of the amount of dust at distances as follows: up to 500 m. 6-8 times, up to 1000 m. 3 times, and up to 2000 m. only by 10%, which indicates that flying soot settles down mainly at distances up to 1000 m. The author proposes: (1) To study the dust content of the air as follows: (a) The dust falling out by the sedimentation method in the size range from 5-10 to 100 $\mu$ . and over; (b) circulating dust by the aspiration method comprising sizes from 1 to 5-10 $\mu$ .; (c) particle count is performed in the range from 0.2 to 3-5  $\mu$ . (2) Glass filters should be used capable of catching up to 95% of particles not larger than 1  $\mu$ . (3) Simultaneously with the dust, microorganisms are determined by the plate method. A new hygienic indicator of air pollution is proposed: acid-alkali reaction, based on the following principle. In winter there is an increase in alkalinity, in summer in acidity; in industrial districts alkalinity is higher, but in residential districts and parks transition to acidity takes place. To combat the escaping gases it is necessary to replace buses

2403

with trolley-buses and to alter the construction of motor engines in such a way as to preclude incomplete combustion. These measures of protection of the purity of the air are based on physiologic, biochemical and biologic methods of examination. Concentrations harmful to the human organism, determined by the use of such methods as testing of reflexes, examination of cellular respiration, adaptometry, eye examination, plethysmography, isotope method, determination of dust content in inspiratory air, etc. Testing of admissible concentrations for atmospheric air revealed the dependence of the tests on hydrogen sulphide, sulphur dioxide and dust.

TRANSLATION: Processes transpiring in a magnetoelastic torque sensor (MTS) are considered, and the corresponding mathematical formulas and equivalent circuits are presented. Verified experimentally formulas for designing MTS are offered. It is proven that the MTS sensitivity only slightly depends on the shaft magnetic permeability, the material of magnetic cores, the supply-voltage frequency, and the design dimensions. The MTS sensitivity is directly proportional to the number of turns of its indicator winding. Both the experiments and calculations show that there exists an optimal value of the excitation current. TITLE: Method of displaying the crystallization front when growing single crystals in the crucibleless zone melting process

SOURCE: Kristallografiya, v. 10, no. 4, 1965, 583-585

TOPIC TAGS: zone melting, single crystal growing, crystallization, silicon

ABSTRACT: The authors have developed a method of displaying the crystallization front of single-crystal silicon by producing bicrystals while rapidly freezing the molten zone. The procedure is illustrated in Fig. 1 of the Enclosure. The crystallization-front growth is monitored by first growing a single crystal of fixed length (~200 mm), producing a molten zone at some distance from the primer (-40 mm), and zone-melting the sample at a given rate. When the zone passes a distance of ~30 mm and the crystallization mode becomes stable, the rotation of the primer is stopped, and the sample heating power is turned off as the zone moves at a fixed speed. The melt and the heated parts are then rapidly cooled. This produces a bicrystal in which the boundary between the single-crystal sections corresponds to the previously existing phase boundary. The next molten zone is produced 30--40 mm above the crystallized section, which now serves as a primer, and the
